**Provect-OX®** Self-Activating ISCO / Enhanced Bioremediation Reagent

Safer, More Effective ISCO using Non-Extreme Persulfate Activation that Yields Sustained, Secondary Biotreatment

When choosing a persulfate-based ISCO reagent, the industry is faced with a growing number of options - with each reagent possessing its self-proclaimed features (Table 1). As described herein, Provect-OX offers some important benefits not inherent to other ISCO alternatives, and it may well be your safest, most effective, most cost-efficient choice.

**Table 1. Comparative Analysis of Select Persulfate-Based ISCO Reagents.**

a Data for PersulfOx and “Base-Activated Persulfate” taken from Regenesis mailer received April 21, 2015.
TWO IMPORTANT ISSUES ASSOCIATION WITH ISCO TECHNOLOGIES

1 = Rebound: Perhaps the main problem with unactivated persulfate or conventional ISCO chemistries summarized above relates to the common problem of contaminant rebound. McGuire et al (2006) summarized this phenomenon well by comparing contaminant removal over time from numerous ISCO projects: a majority of the ISCO sites analyzed exhibited: i) initial (perhaps significant) contaminant reduction (dissolved phase) followed by ii) contaminant rebound within a few years’ time (Figure 1). This is a response of initial oxidation reactions degrading targeted organic compounds in the dissolved phase, but once the reactive species were consumed or exhausted, nothing remained to deal with compounds that desorbed from the aquifer matrix. This led to rebound over time, with the degree of rebound being a function of multiple factors such as oxidant loading rate, soil type and texture, hydrogeological conditions, microbiological attenuation, et cetera (Tsitonaki et al., 2010; Watts, 2011).

To manage rebound, Provect-OX employs ferric iron to activate persulfate (Scalzi and Karachalios, 2013). This unique chemistry yields very effective, short-term ISCO (see below) but also enhances bioremediation processes over an extending period of time. This is accomplished via the subsequent utilization of sulfate and iron as terminal electron acceptors for facultative reductive processes. Degradation intermediates generated during oxidation of contaminants and other naturally occurring organics such as humic acids may act as electron shuttles, allowing the reduction of Fe(III) to Fe(II) in the redox cycling of iron and continued activation of persulfate. This combined remedy provides supplemental treatment mechanisms thereby allowing for more cost-efficient dosing of the product.

Alternative methods of stimulating secondary biodegradation processes using oxygen release compounds (such as calcium or magnesium oxyhydroxide) are limited in that they will remain active for only a few months, after which time their oxygen release potential is exhausted. In addition, the released oxygen will tend to migrate into the vadose zone where it may not provide any benefit in terms of groundwater...
Provect-OX®
Comparative Analysis of ISCO Alternatives

Provect-OX employs multiple oxidation chemistries which gives it a wide range of oxidant activity:

- Persulfate radical
- Ferrate
- Persulfate

Persulfate is activated by Fe III which requires a lower activation energy than alternative mechanisms while not consuming the oxidant. Activation is believed to be a result of the transiently elevated oxidation state of the iron to a supercharged iron ion (Fe\(^{+6}\) or ferrate), which itself may act as an oxidant. As this supercharged iron cation is consumed, the resulting ferric species can act as a terminal electron acceptor for biological attenuation. Coincidentally, the generated sulfate ion from the decomposition of the persulfate provides a terminal electron acceptor for sulfate reducers which may further remediate the targeted compounds in the groundwater and soils. The reactions that occur in the chemical oxidation include persulfate radicals and ferrate, as summarized below (Equation 1):

\[
S_2O_8^{2-} + Fe^{+3} \rightarrow Fe^{(+4 to+6)} + SO_4^{2-} + SO_4^{2-}\bullet \quad (\text{Eq. 1})
\]

**BENEFITS OF PROVECT-OX COMPARED TO OTHER PERSULFATE-BASED ISCO TECHNOLOGIES**

- **More Effective**: Promotes multiple oxidation reactions and free radicals yielding the most effective situ oxidation of a wide-range of organic contaminants. Also provides a unique microbiological component for multiple accelerated attenuation processes.

- **More Efficient**: Significantly lower costs as a result of multiple oxidants and secondary treatment processes. Use of ferric oxide conserves oxidant when compared to EDTA-FeIII chelated iron activation.

- **Safer**: Fewer health and safety concerns as compared to use of traditional activation methods such as heat, chelated metals, and hydrogen peroxide or pH extremes using NaOH.
  - Contains built-in activation which eliminates the need for additional and potentially hazardous chemicals required to achieve traditional persulfate activation.
  - Will not generate excessive heat / off-gases
Easy to Use: Single component product with integrated activator results in simplified logistics and application. Made in USA and Europe.
- No additional containers or multi-step mixing ratios required prior during field application
- Fewer handling logistics and equipment compatibility issues
- No secondary containment requirements

Improved Performance: Combined remedy maximizes the inherent geochemistry of a “post-oxidation” environment for biologically based attenuation to prevent “rebound”.
- The ferrous iron and the sulfide promote the formation of pyrite to combat the toxic effects of sulfide and hydrogen sulfide accumulation while also providing a means of removing targeted organic and inorganic contaminants via precipitation reactions. Moreover, pyrite possesses a high number of reactive sites that are directly proportional to both its reductive capacity and the rate of decay for the target organics
- Will not mobilize heavy metals or lead to the generation of secondary impact issues such as elevated arsenic, chromium resulting from grossly elevated pH.

Longevity. Uniquely supports long-term, sustained (>2 years), secondary bioremediation processes to manage residuals and prevent contaminant rebound. Iron will remain in place and active for many years.
